Abstract
Methods for the in situ generation of dichloroindium hydride (HInCl₂) via the reduction of InCl₃ with various reducing agents, such as tributyltin hydride (tributylstannane; Bu₃SnH), diisobutylaluminum hydride (DIBAL-H), triethylsilane (Et₃SiH), lithium aminoborohydride (LAB), and sodium borohydride (NaBH₄), in various solvents are reviewed and compared. The use of the InCl₃/NaBH₄ system in addition to forming HInCl₂, also generated borane that was trapped as BH₃-tetrahydrofuran (THF). Carefully controlling the activity of these reducing agents allows for the selective and/or partial reduction of multi-functionalized compounds containing nitriles and halogens.

Keywords: Dichloroindium hydride, HInCl₂, InCl₃, NaBH₄, borane, reduction

1. Introduction

The use of metal-mediated reactions has played an important role in the development and advancement of organic chemistry with far reaching effects spanning novel laboratory techniques to vital industrial applications. Among the many uses of metals, metal hydride reductions of functional groups are among the most common and useful chemical transformations. Traditional and commonly used metal hydrides like sodium borohydride (NaBH₄) and lithium aluminum hydride (LiAlH₄) form an integral part of the modern organic chemist’s toolbox. While both hydrides are used extensively, the ability of LiAlH₄ to reduce most functional groups limits its use in the reduction of multifunctional compounds when selective reduction is desired. Conversely, NaBH₄ is a mild reducing agent with limited abilities in the reduction of many functional groups such as nitriles and carboxylic acids. Sodium borohydride is known to selectively reduce ketones and aldehydes in the presence of other functional groups. Many alternatives have recently been developed to safely and selectively reduce several functional groups at will. Among these alternatives, a variety of Group 13 metal hydride derivatives have been developed over the years, some of which are extensively utilized.

Indium has recently garnered attention in metal-mediated reactions due in part to the relatively low oxidation potentials of the most common oxidation states of indium: In⁺ (0.14 V) and In³⁺ (0.44 V). These oxidation potentials tend to produce favorable reaction conditions for the synthesis of organoindium compounds under ambient conditions.

Indium hydride reagents (LiInH₄, LiPhInH₃, and LiPh₂InH₂) were first prepared from InCl₃ and LiH by Wiberg and Schmidt and were later explored by Butsugan and coworkers who further demonstrated their ability to reduce a variety of functional groups including aldehydes, ketones, esters, and halides. Subsequently, other indium hydride reagents have been developed. In the next section, we give an overview of the generation of dichloroindium hydride (HInCl₂) and its application to various reductions in organic synthesis.

2. Preparation of Dichloroindium Hydride (HInCl₂)

2.1 Generation of HInCl₂ using Bu₃SnH

Dichloroindium hydride was first prepared by Baba and coworkers by the reduction of InCl₃ with tributyltin hydride (tributylstannane; Bu₃SnH) (Scheme 1).
Scheme 1. Generation of dichloroindium hydride.\textsuperscript{8}

The \textit{in situ} generated HInCl\textsubscript{2} arising from the reduction of InCl\textsubscript{3} with Bu\textsubscript{3}SnH was able to reduce a variety of functionalities including aldehydes, ketones and alkyl halides.\textsuperscript{8} Interestingly, the InCl\textsubscript{3}/Bu\textsubscript{3}SnH system was found to effect stereoselective reductive aldol reactions affording both \textit{syn} and \textit{anti} selectivity depending on the solvent used (Scheme 2).\textsuperscript{9}

Scheme 2. Selective reductive aldol reactions of \(\alpha,\beta\)-unsaturated ketones.\textsuperscript{9}

The use of anhydrous THF favored the \textit{anti} product (\textit{syn:anti} 5:95), while the use of methanol or H\textsubscript{2}O/THF favored the \textit{syn} derivative (\textit{syn:anti} 99:1 and 95:5 respectively). Additionally, acid chlorides have been partially reduced to the corresponding aldehyde in the presence of triphenylphosphine (PPh\textsubscript{3}) along with HInCl\textsubscript{2} generated using a catalytic amount of InCl\textsubscript{3} and one equivalent of Bu\textsubscript{3}SnH (Scheme 3).\textsuperscript{10}

Scheme 3. Proposed catalytic cycle for acid chloride reductions.\textsuperscript{10}
The catalytic cycle proposed by Baba and coworkers proceeds via the coordination of PPh$_3$ to InCl$_3$ followed by a hydride transfer from the Bu$_3$SnH to the InCl$_3$ to generate HInCl$_2$, which then reduces the acid chloride to the corresponding aldehyde and regenerates the InCl$_3$.$^{10}$ Dichloroinium hydride was also found to be an efficient radical initiator catalyzing the reduction of organic halides (Table 1).$^{11a}$

**Table 1. InCl$_3$/Bu$_3$SnH reduction of halides**$^{11a}$

$^a$InCl$_3$ 0.1 mmol, Bu$_3$SnH 1 mmol, RX 1 mmol, THF 2 mL, rt. $^b$Bu$_3$SnH (3 mmol) was used

The proposed catalytic cycle for the reduction of organic halides suggests a radical dehalogenation mechanism wherein the In-H bond is cleaved to allow formation of the indium radical, which then reacts with organic halides (Scheme 4).$^{11a}$
Scheme 4. Proposed catalytic cycle for the dehalogenation of organic halides.\textsuperscript{11a}

More recently, this system has been effectively used in the generation of allylic indium through the hydroindation of 1,3-dienes that react with carbonyl or imine compounds in a one-pot reaction sequence.\textsuperscript{11b} For example, 1,4-diphenyl-1,3-butadiene underwent hydroindation and upon the addition of an aliphatic aldehyde, 3-phenylpropanal, gave the allylated product in 88\% yield.\textsuperscript{11b} However, because of the toxicity of Bu\textsubscript{3}SnH, alternative reducing agents should be considered to obtain HInCl\textsubscript{2}.

2.2 Generation of HInCl\textsubscript{2} using DIBAL-H
Oshima and coworkers developed an alternative method of generating HInCl\textsubscript{2} using diisobutyl-aluminum hydride (DIBAL-H) as the hydride source to reduce InCl\textsubscript{3} (Scheme 5).\textsuperscript{12} Dichloroindium hydride was produced and used along with triethylborane (Et\textsubscript{3}B) to carry out the hydroindation of a variety of alkynes to the corresponding (Z)-alkenes (Table 2).\textsuperscript{12}

\[
\text{InCl}_3 + \text{DIBAL-H} \rightarrow \text{HInCl}_2 + \text{DIBAL-Cl}
\]

Scheme 5. Generation of HInCl\textsubscript{2} with DIBAL-H.\textsuperscript{12}

Oshima suggests that the addition of Et\textsubscript{3}B promotes the reaction by acting as a radical initiator that facilitates the radical addition of HInCl\textsubscript{2} across the carbon-carbon triple bond. Additionally, HInCl\textsubscript{2} and Et\textsubscript{3}B in the presence of dioxygen were found to promote radical cyclizations via the generation of an ethyl radical, which then reacts with HInCl\textsubscript{2} to provide an indium-centred radical ·InCl\textsubscript{2}.\textsuperscript{13} The generated ·InCl\textsubscript{2} then reacts with iodine to form the radical.
intermediate 2 which subsequently cyclizes to afford 3 followed by a hydrogen atom abstraction from HInCl₂ to regenerate ·InCl₂ and afford the final product 4 (Scheme 6).\textsuperscript{13}

**Scheme 6.** Proposed catalytic cycle of the radical cyclizations of halo acetals.\textsuperscript{13}

Chemoselective reductions of alkyl bromides and carbonyl functionalities using HInCl₂ were also explored.\textsuperscript{13} Interestingly, alkyl bromides were found to undergo exclusive reduction in the presence of ester and ketone functionalities, but aldehydes were found to undergo reduction faster than alkyl bromides.\textsuperscript{13}
2.3 Generation of HInCl₂ using silanes

Mixtures of silanes and InCl₃ have also been used to carry out a variety of reductions. The combination of chlorodimethylsilane and InCl₃ was first used to catalyze the reductive Friedel–Crafts alkylation of various aromatics with carbonyl compounds (Scheme 7).¹⁴

\[
\text{R}_1\text{R}_2\text{C}=\text{O} + \text{ArH (excess)} \xrightarrow{\text{InCl₃/Me₂SiCl}} \text{R}_1\text{R}_2\text{Ar}
\]

**Scheme 7.** Friedel–Crafts alkylation with aromatic carbonyl compounds.¹⁴

Subsequently, reductive deoxygenation of aryl ketones was achieved using chlorodimethylsilane and InCl₃ (Scheme 8).¹⁵

\[
\text{ArC}=\text{O} \xrightarrow{\text{InCl₃/Me₂SiCl, CH₂Cl₂, 25 °C}} \text{ArCH}_2\text{R}
\]

**Scheme 8.** Reductive deoxygenation of various ketones.¹⁵

This mixture of chlorodiphenylsilane and InCl₃ has also been shown to bring about analogous reductive deoxygenations of a variety of secondary and tertiary alcohols (Scheme 9).¹⁶

**Scheme 9.** Reduction of various alcohols.¹⁶
Additionally, the system was found to give high chemoselectivity for hydroxyl groups in the presence of other functional groups, such as esters, as exemplified by the selective deoxygenation of hydroxy-esters (Scheme 10).\textsuperscript{16}

\]

\textbf{Scheme 10}. Direct chemoselective reduction of alcohols by Ph\textsubscript{2}SiHCl/InCl\textsubscript{3}.\textsuperscript{16}

It was proposed that InCl\textsubscript{3} acts as a Lewis acid that loosely coordinates to oxygen to accelerate the deoxygenation of the resulting intermediate by promoting a hydride transfer from silane.\textsuperscript{16} While the generation of HInCl\textsubscript{2} was not reported in these earlier studies, the \textit{in situ} formation of HInCl\textsubscript{2} may also explain the observed reductions. Later studies of InCl\textsubscript{3} with other silanes including triethylsilane (Et\textsubscript{3}SiH), have proposed the \textit{in situ} generation of HInCl\textsubscript{2} and its use in reductive aldol reactions (Scheme 11).\textsuperscript{17}

\end{align*}
\]

\textbf{Scheme 11}. Diastereoselective aldol reactions.\textsuperscript{17}

Interestingly, InBr\textsubscript{3} was also found to undergo a similar reduction in the presence of Et\textsubscript{3}SiH to generate HInBr\textsubscript{2} which was used in a variety of diastereoselective reductive aldol reductions.\textsuperscript{17}
Mechanistically, it was suggested that HInX₂ is generated by the slow transmetallation of InX₃ with Et₃SiH which then undergoes a 1,4-addition to the enone to afford the indium enolate 1. Subsequent reaction of 1 with 2 via a Zimmerman–Traxler six-membered cyclic transition state ultimately affords the product 4.¹⁷

**Scheme 12.** Plausible mechanistic cycle.¹⁷

Further exploration of the InCl₃/Et₃SiH system revealed its ability to reduce alkyl bromides in addition to the intramolecular cyclization of enynes via the hydroindation of alkynes. The proposed mechanism proceeds via the formation of the vinyl radical which cyclizes to the alkene product. For example, diethyl allylpropargylmalonate afforded the cyclized exo-methylene compound in a 53% yield (eq. 1, Scheme 13).¹⁸a Additionally, Baba and coworkers have also demonstrated the inter- and intramolecular radical coupling of ene-ynes and halo-alkenes using the InCl₃/MeONa/Ph₂SiH₂ system.¹⁸b For example, iodobenzene and acrylonitrile gave the coupled 3-phenylpropanenitrile product in a 60% yield (eq. 2, Scheme 13).¹⁸b

The versatility of the InCl₃/Et₃SiH system to generate HInCl₂ has also been extended to the reduction of organic azides to the corresponding amines in a highly chemoselective fashion (Scheme 14).¹⁹

Additionally, γ-azidonitriles cyclize to afford pyrrolidin-2-imines (Scheme 15).¹⁹ The authors propose the γ-azidonitriles undergo a radical cyclization similar to that of the aforementioned cyclization of enynes.

More recently, the chemoselective reductive amination of carbonyl compounds has also been demonstrated by Yang and coworkers using the InCl₃/Et₃SiH system (Scheme 16).²⁰

Scheme 16. Reductive amination of aldehydes and ketones with various amine salts.$^{20}$

The system can be applied to a variety of cyclic, acyclic, aromatic and aliphatic amines in the presence of functionalities such as esters, hydroxyls, carboxylic acids and olefins. NMR and ESI-
MS were used to help elucidate a mechanism and found the existence of a stable methanol-coordinated indium(III) species which they postulate to be responsible for the generation of indium hydride (Scheme 17).²⁰

Scheme 17. Proposed mechanism for the InCl₃/Et₃SiH/MeOH system-promoted reductive amination.²⁰

Sakai and coworkers have further explored the scope of the reductive capabilities of indium hydride with various carbonyl compounds. Tertiary amides were directly reduced to the corresponding tertiary amines using InBr₃/Et₃SiH (Scheme 18).²¹

Scheme 18. Reduction of amides to amines.²¹

Interestingly, the reduction of carboxylic acids to primary alcohols or deoxygenation to diphenylmethanes using a similar system with the addition of an aromatic compound has recently been reported.²² Aromatic carboxylic acids with the addition of aromatic compounds were fully reduced to the corresponding diphenylmethanes using this system. Sakai and coworkers also describe an efficient method for directly converting carboxylic acids into the corresponding primary alcohols using InBr₃ and tetramethyl disiloxane (TMDS) (Scheme 19).²²
Scheme 19. Synthesis of primary alcohols from aliphatic carboxylic acids.\(^{22}\)

2.4 Generation of HInCl\(_2\) using NaBH\(_4\)

Although HInCl\(_2\) has great potential as a mild reducing agent, some of the methods previously used for its synthesis utilize less than ideal conditions and reagents. The HInCl\(_2\)/NaBH\(_4\) reagent system has received significant attention due to the simple and convenient in situ preparation of HInCl\(_2\).\(^{23}\) NaBH\(_4\) is less expensive and a less toxic than Bu\(_3\)SnH originally used to prepare HInCl\(_2\).\(^8\) Dichloroindium hydride was first generated with NaBH\(_4\) by Baba and coworkers when exploring alternative hydride sources to the tin hydride originally used (Scheme 20).\(^{23}\)

\[
\begin{align*}

\end{align*}
\]

Scheme 21. Intramolecular cyclization of 1-allyloxy-2-iodobenzene.\(^{23}\)

Representative HInCl\(_2\)/NaBH\(_4\) intermolecular radical additions were also demonstrated using iodobenzene and electron-deficient olefins (Scheme 22).\(^{23}\)

\[
\begin{align*}
\text{I} + \xrightarrow{\text{InCl}_3 (0.1 \text{ eq.})/\text{NaBH}_4 (1.2 \text{ eq.})} \quad 57\%
\end{align*}
\]

Scheme 22. Radical addition of iodobenzene to electron-deficient olefins.\(^{23}\)
In subsequent work, Ranu and coworkers used the InCl$_3$/NaBH$_4$ system to generate HInCl$_2$ and chemoselectively reduced conjugated alkenes (Scheme 23).\textsuperscript{24,25}

\[
\begin{array}{c}
R^1 = \text{alkyl, aryl} \\
R^2 = \text{H, Me, CN} \\

\end{array}
\rightarrow
\begin{array}{c}
R^1 = \text{alkyl, aryl} \\
R^2 = \text{H, Me, CN} \\
E^1, E^2 = \text{CN, H, CO$_2$Et}
\end{array}
\]

\textbf{Scheme 23.} Reduction of carbon-carbon double bond of conjugated alkenes.\textsuperscript{24}

This system was shown to reduce selectively a variety of conjugated alkenes such as, $\alpha,\alpha$-dicyano olefins, $\alpha,\beta$-unsaturated nitriles, cyanoesters, cyanophosphonate and dicarboxylic esters. Interestingly, the attempted reduction of chalcones produced a mixture of saturated ketones and alcohols when quenched with H$_2$O and exclusively saturated alcohols when quenched with MeOH.\textsuperscript{24} Similarly, Ranu and coworkers also found that the InCl$_3$/NaBH$_4$ system selectively reduces $\alpha,\beta$-carbon-carbon double bond in $\alpha,\beta$-$\gamma,\delta$-unsaturated diaryl ketones, dicarboxylic esters, cyano esters and dicyano compounds (Scheme 24).\textsuperscript{26}

\[
\begin{array}{c}
R^1 = \text{alkyl, aryl} \\
R^2 = \text{H, Me, CN} \\
E^1, E^2 = \text{CN, H, CO$_2$Et}
\end{array}
\rightarrow
\begin{array}{c}
R^1 = \text{alkyl, aryl} \\
R^2 = \text{H, Me, CN} \\
E^1, E^2 = \text{CN, H, CO$_2$Et}
\end{array}
\]

\textbf{Scheme 24.} Selective reduction of $\alpha,\beta$-carbon-carbon double bonds.\textsuperscript{26}

Ranu and coworkers have also demonstrated the ability of the InCl$_3$/NaBH$_4$ system to synthesize (E)-alkenes through the stereoselective reduction of vic-dibromides (eq. 1, Scheme 25),\textsuperscript{27} as well as the selective reduction of 2,3-epoxybromides to the corresponding allylic alcohols (eq. 2, Scheme 25).\textsuperscript{28} Interesting reactions using alkynes have also been developed using the InCl$_3$/NaBH$_4$ system, including the dimerization of terminal alkynes to enynes (eq. 3, Scheme 25).\textsuperscript{29}

Others have continued to explore the InCl$_3$/NaBH$_4$ system and its reaction with alkynes. Pan and coworkers have been able to stereoselectively synthesize (E)-2-arylvinylyphosphonates through the hydroindation and subsequent hydrolysis of aryl alkyl phosphonates (Scheme 26).\textsuperscript{30} They were able to expand this methodology to the coupling of terminal alkynes with aryl halides to give disubstituted (E)-alkenes.\textsuperscript{31}

Although a considerable number of studies have examined the InCl$_3$/NaBH$_4$ system, few have reported on the significant influence that solvent can have on reaction rates and yields of reductions.\textsuperscript{23,31} For example, Baba and coworkers report that alkyl halides were reduced
efficiently (up to 78% reduction) using a catalytic amount of InCl$_3$ along with one equivalent of NaBH$_4$ in MeCN (Table 3, entry 4). However, the same reaction is low yielding in THF (only 15% reduction) under otherwise similar reaction conditions (Table 3, entry 5).$^{23}$ Similar solvent effects were observed by others working with HInCl$_2$.$^{31}$

![Scheme 25](image)

Scheme 25. Dimerization of terminal alkynes to enynes.$^{29}$

![Scheme 26](image)

Scheme 26. Synthesis of (E)-2-arylvinylphosphonates using the InCl$_3$/NaBH$_4$ system.$^{30}$

Since previous reports had not elucidated the origin of these solvent effects, we decided to explore the InCl$_3$/NaBH$_4$ reagent system further by monitoring the boron species formed during the reaction via $^{11}$B NMR spectroscopy.$^{32}$ Consequently, we reacted a 1:1 molar ratio of InCl$_3$ to NaBH$_4$ in both THF and MeCN and analyzed the supernatant solution by $^{11}$B NMR spectroscopy to probe the identity of the boron species formed in situ (Scheme 27).$^{32}$

Scheme 27. Reaction of InCl₃/ NaBH₄ in THF and MeCN

¹¹B NMR spectral analysis of InCl₃/NaBH₄ in THF (Scheme 27, equation 1) revealed the formation of a borane-tetrahydrofuran complex (BH₃·THF). When the same reaction was run in MeCN (Scheme 27, equation 2), a significantly different ¹¹B NMR spectrum was observed. A BH₂ species was observed, which we believe is the result of the reduction of the MeCN solvent by borane.

We suggest that the poor reduction of alkyl halides using a catalytic amount of InCl₃ along with one equivalent of NaBH₄ in THF that was previously reported is likely to have been due to the inhibition of the catalytic cycle by the in situ generated BH₃·THF. Consequently, when a stoichiometric amount of InCl₃ was used along with three equivalents of NaBH₄, (3-bromopropyl)benzene was fully reduced to n-propylbenzene with an isolated yield of 80%, indicating that BH₃·THF or the solvent THF has little effect on stoichiometric reductions involving HInCl₂. Based on the ¹¹B NMR spectral data, we postulated that the InCl₃/NaBH₄ system in THF should reduce nitriles efficiently. After some optimization we found that 1 equivalent of InCl₃ and 3 equivalents of NaBH₄ in THF was the optimum ratio to reduce aromatic, heteroaromatic, and aliphatic nitriles the corresponding primary amine (Scheme 28).
Scheme 28. InCl₃/NaBH₄ reduction of aromatic, heteroaromatic and aliphatic nitriles to primary amines.³²

The InCl₃/NaBH₄ system was able to reduce a variety of aromatic nitriles, including aromatic nitriles with electron-donating groups in good to excellent yields (70-99%). A variety of halogen-substituted aromatic nitriles were also reduced using this simple procedure. Although the reduction of benzyl and aliphatic nitriles is typically more challenging due to the acidity of the α–hydrogens, which tend to be deprotonated under some reaction conditions,³⁴ the InCl₃/NaBH₄ system in THF readily reduced these substrates to their corresponding primary amine in good to excellent yields. Nitriles containing heteroaromatic rings, such as thiopheneacetonitriles, were also nicely reduced using this system.

2.5 Generation of HInCl₂ using lithium aminoborohydride (LAB)
We have recently explored alternative methods of producing HInCl₂ by the reduction of InCl₃ using LAB reagents previously discovered in our laboratory.³⁵ The experiments were carried out by reacting one to three equivalents of anhydrous InCl₃ with one to three equivalents of lithium dimethylaminoborohydride (MeLAB) in THF for 1 h at 25 °C. The reactions were then evaluated by obtaining the ¹¹B NMR spectrum of the supernatant solution under an inert atmosphere. It was discovered that the ratio of InCl₃ to MeLAB played a significant role in the formation of the reducing species (Table 4).³²

When an excess of MeLAB was used (Table 4, entries 1 and 2), the reaction mixture quickly turned dark grey and precipitated colloidal indium metal which aggregated to form a shiny indium nugget. From the weight of the indium metal, it was deduced that indium metal was formed essentially quantitatively in these reactions. Our results indicate that two equivalents of MeLAB reagent were sufficient to fully reduce InCl₃ to indium metal in a quantitative manner (Table 4, entry 2). However, when two or more equivalents of InCl₃ were used and one equivalent of MeLAB was added slowly over 5 minutes (Table 4, entries 4 and 5), little or no indium metal was generated and only a slight browning of the reaction mixture was observed. ¹¹B NMR spectroscopy revealed the complete disappearance of the MeLAB quartet at δ -15 ppm and the appearance of a corresponding aminoborane [BH₂N(CH₃)₂]₄ complex that we believe to be a dimmer, with a triplet at δ 5 ppm.³²
It was also found that the HInCl₂ produced using the MeLAB/InCl₃ reagent system possesses similar reductive capabilities to that of HInCl₂ prepared via other methods. For example, we were able to reduce aliphatic halides like (3-bromopropyl)benzene to n-propylbenzene in 77% yield (Scheme 29).³²

2.6. Tandem, selective and partial reduction of halides and nitriles using HInCl₂

As discussed above, dichloroindium hydride can be synthesized by a variety of methods. The method and the reaction conditions utilized can have a profound effect on the reaction outcome. We suggest that these dramatic differences can in part be explained by the reaction of by-products generated during the synthesis of HInCl₂. This allows for the customization of the reductive capabilities depending on the method used to prepare HInCl₂ (Scheme 30).
Scheme 30. Various methods of generating HInCl₂.

2.6.1 Tandem reductions using HInCl₂ and BH₃·THF. While our previous study demonstrated the ability of InCl₃/NaBH₄ to reduce nitriles to primary amines utilizing in situ generated BH₃·THF, we also sought to explore the reductive capabilities of the mixture of HInCl₂ and BH₃·THF. This was achieved by investigating a tandem reduction sequence that utilized both the HInCl₂ and BH₃·THF generated in situ from the InCl₃/NaBH₄ system (Scheme 31).

Scheme 31. Generation of HInCl₂ and BH₃·THF.

Since HInCl₂ is known to reduce alkyl halides, 4-(bromomethyl)benzonitrile and 4-(chloromethyl)benzonitrile underwent the expected tandem reduction to afford 4-methylbenzylamine in isolated yields of 85% and 65%, respectively. Similarly, using the InCl₃/NaBH₄/THF system, 6-bromohexanenitrile was found to undergo the tandem reduction of both the halide and nitrile using the InCl₃/NaBH₄ system in THF to afford hexan-1-amine in an isolated yield of 68%, clearly demonstrating the reductive potential of HInCl₂ and BH₃·THF generated in situ from the InCl₃/NaBH₄ system in THF (Scheme 32).
Scheme 32. Tandem reduction of halo nitriles using InCl₃/NaBH₄/THF.

2.6.2 Selective reduction of halides in the presence of nitriles. We next turned our attention to the selective reduction of halides in the presence of nitriles using the InCl₃/NaBH₄ system. The main obstacle envisioned for this reaction was the selective scavenging of BH₃·THF from the mixture of HInCl₂ and BH₃·THF. Attempts were made to capture the generated borane with tetramethylethylenediamine (TMEDA), which is known to readily complex with BH₃ to form (BH₃)₂·TMEDA. However, TMEDA also tightly complexed HInCl₂ and prevented it from reducing carbon-halogen bonds. This result prompted us to revisit the MeLAB/InCl₃ system which previously reduced (3-bromopropyl) benzene to the corresponding n-propylbenzene in 77% yield. We anticipated that this system would give selective reductions of carbon-halogen bonds in the presence of nitriles (Scheme 33).

Scheme 33. Generation of HInCl₂ with MeLAB.

After some optimization, the MeLAB/InCl₃ system was found to selectively reduce alkyl halides in the presence of nitriles as evidenced by the reduction of 4-(bromomethyl)benzonitrile and 4-(chloromethyl)benzonitrile to p-tolunitrile in isolated yields of 70% and 94%, respectively (Scheme 34).

Scheme 34. Selective reductions using MeLAB/InCl₃.
As noted earlier, MeCN was found to be an excellent borane scavenger and generated only HInCl₂ from the InCl₃/NaBH₄ system. This property of MeCN along with the ability of HInCl₂ to reduce halides was utilized to selectively reduce 4-(bromomethyl)benzonitrile and 4-(chloromethyl)benzonitrile to p-tolunitrile in an isolated yield of 98% and 68%, respectively (Scheme 35).

Scheme 35. Selective reduction using InCl₃/NaBH₄/MeCN.

2.6.3 Tandem, selective, and partial reduction of halo-nitriles using DIBAL-H and InCl₃.

Lastly, generation of HInCl₂ using DIBAL-H was also explored and utilized to selectively reduce halides in the presence of nitriles. As previously mentioned, Oshima and coworkers demonstrated the generation of HInCl₂ using InCl₃/DIBAL-H. We were able to utilize HInCl₂ generated via Oshima’s procedure to selectively reduce 4-(bromomethyl)benzonitrile and 4-(chloromethyl)benzonitrile to p-tolunitrile in isolated yields of 85% and 74%, respectively (Scheme 36).

Scheme 36. Selective reduction using InCl₃/DIBAL-H.

It is well established that DIBAL-H can partially reduce nitriles to aldehydes. Interestingly, DIBAL-H selectively and partially reduces 4-(bromomethyl)benzonitrile and 4-(chloromethyl)benzonitrile to the corresponding aldehydes in very good yields (Scheme 37).

Scheme 37. Selective partial reductions using DIBAL-H.
Sequential addition of two equivalents of DIBAL-H followed by addition of InCl₃ afforded an efficient tandem reduction reaction of halo nitriles. The first equivalent of DIBAL-H partially reduced the nitrile functionality while the second equivalent of DIBAL-H, in conjunction with InCl₃, reduced the carbon-halogen bond. This was exemplified by the tandem reduction of 4-(bromomethyl)benzonitrile and 4-(chloromethyl)benzonitrile to 4-methylbenzaldehyde in 67% and 63%, respectively (Scheme 38).

3. Conclusions

Generation of HInCl₂ using a variety of hydride sources, such as: Bu₃SnH, Et₃SiH, NaBH₄, DIBAL-H, and MeLAB, is comparatively reviewed. The methods of HInCl₂ generation and the reaction by-products allowed for tailoring of the systems towards tandem, selective and partial reductions of halo nitriles. The InCl₃/NaBH₄/THF system was found to efficiently reduce both nitriles and carbon-halogen bonds in a tandem fashion utilizing both HInCl₂ and BH₃·THF. In comparison, the InCl₃/NaBH₄/MeCN system, in which acetonitrile scavenges the *in situ* generated borane and affords the selective reduction of the carbon-halogen bond in halo nitriles. Similarly, the InCl₃/MeLAB and the InCl₃/DIBAL-H systems were also found to selectively reduce the carbon-halogen bond in halo nitriles, while DIBAL-H alone selectively reduced halo nitriles to the corresponding halo aldehyde. The sequential addition of two equivalents of DIBAL-H followed by the addition of an equivalent of InCl₃ allowed the partial reduction of halo nitriles to halo imines and subsequent reduction of the carbon-halogen bond to afford the corresponding aldehyde in a one-pot procedure.
