Abstract
This work describes a study of the α/β-diastereoselectivity of the hydrogenation of phosphonylated exoglycals in the galactofuranose series. Nine exoglycals displaying sterically hindering groups on the α or the β face have been synthesized and hydrogenated using Pearlman's catalyst. These reactions gave the expected C-glycoside with good to excellent α-selectivities.

Keywords: Exoglycal, C-glycoside, hydrogenation, phosphonate

Introduction

In the course of our study involving the exploration of the mechanism of glycosyl processing enzymes, we have developed an approach to generate C-glycosidic phosphonates in the galactofuranose series (Gal\(\text{f}\)). First we developed conformational probes mimicking UDP-Gal\(\text{f}\) the substrate of key enzymes implied in the biosynthesis of the mycobacterial cell wall: UDP-galactose mutase (UGM) and Galactofuranosyl transferases.\(^{1,2}\) We then prepared nucleotide-exoglycals, fluorinated\(^3\) or not,\(^4\) that displayed interesting time-dependent inactivation properties against UDP-galactose mutase.

In our studies, exoglycals became key intermediates: for instance we found that once protected with four TBDMS groups, the enol ether could be hydrogenated selectively to give a α-phosphonate (Scheme 1) thus yielding a C-glycosidic analog of the natural Gal\(\text{f}\)-1-α-phosphate.\(^4\) In some cases, glycoconjugates whose anumeric configuration is inverted compared to the natural substrate displayed interesting inhibition properties.\(^5\) A survey of the literature in the Gal\(\text{f}\) series showed that there is no published method to synthesize the corresponding Gal\(\text{f}\)-1-β-
phosphonate. Therefore, we addressed the question of the obtention of β-phosphonates from phosphonlated exoglycals.

The purpose of this study is to define the α/β stereoselectivity of the hydrogenation as a function of the protective group pattern of the phosphonylated exoglycal. Since both α and β diastereomers can be transformed into biologically relevant molecules, we found it interesting to assess the scope of these hydrogenations as a function of i) the selective steric hindrance of one of the two faces of the exoglycal ii) the directing effect of a OH group at the 2- or the 3- or the 5-position of the galactofuranosyl moiety (scheme 1). In the early eighties, it had already been acknowledged that hydroxyl-directed hydrogenations are of considerable generality.8,9 The addition of hydrogen usually occurs from the same face of a cyclic system than the directing group.8,9 Thus, we developed the chemistry to differentiate the 2- and the 3-positions of the starting exoglycal and selectively install a hindering group, or a OH group, on either face of the carbohydrate (Scheme 1).

Scheme 1

Results and Discussion

Selective protections of the intermediate lactones

First, we developed a synthetic pathway for selectively protecting the 3-position of the starting d-1,4-galactonolactone.

The synthesis starts from known 5,6-O-(dimethyl-methyldiene)-d-galactono-1,4-lactone 1 (Scheme 2).10 Despite the steric hindrance of the 5 and 6 positions, alcohol 1 was selectively silylated in presence of a slight excess of TBDMSCl giving 2 in 85% yield. This regioselectivity may be explained by the fact that the carbonyl group of the lactone decreases the pKa of the adjacent secondary alcohol, thus increasing its reactivity towards electrophiles. Intermediate alcohol 2 was transformed into lactone 3 (in 93% yield) by addition of pivaloyl chloride. This key intermediate is of particular interest since all the secondary alcohols in lactone 3 are differentiated. Under published conditions (AcOH/H2O, 60°C),10 the acetonide could be hydrolyzed to afford an intermediate 5,6-diol 4 in an expected 60% yield. This moderate yield can be explained by the concomitant deprotection of the TBDMS group at the 2-position (the resulting triol 5 was isolated in 8%). However, we had planned to install two TBDMS groups at
positions 5 and 6: therefore, instead of isolating intermediate diol 4, we performed the persilylation on the crude hydrolysis mixture yielding 6 in 74% yield for two steps.

**Scheme 2.** a) TBDMSCl, Im, DMF (85%) b) PivCl, Py, CH$_3$CN, 80°C (93%) c) AcOH, H$_2$O, 60°C. d) conditions c then TBDMSCl, Im, DMF, 60°C (74%).

**Synthesis of the phosphorylated exoglycals**

From lactones 3 and 6 we could synthesize two exoglycals 7 and 8 according to the one-pot procedure developed by Lin *et al.* in 72 and 76% yield, respectively (Scheme 3).$^{11,12}$

**Scheme 3.** a) LiCH$_2$PO(OMe)$_2$ then (CF$_3$CO)$_2$O, Py. b) MeOH, NaH, RT. c) TBAF, THF (73%). d) DCC, HCO$_2$H, RT (79%). e) Ac$_2$O, Py, RT (96%).

Since their protective groups patterns were orthogonal, the two key molecules 7 and 8 could easily be transformed into a broad range of exoglycals presenting different functional groups on all the four available alcohols of the galactofuranose moiety. The pivaloates could be chemoselectively hydrolyzed without deprotection of the TBDMS, the acetonide or the phosphonate methyl esters, to give alcohol 9 and 13 in 67 and 68% yield, respectively. A TBAF deprotection could in turn lead to alcohol 10 that was further acylated into formate 11 and acetate 12. At this stage we had in hand seven exoglycals (molecules 7 to 13) that could be used in
hydrogenation assays. This series of molecules can be divided into two families: the first one displays a sterically hindering TBDMS group at the 2-position (α face of the exoglycal) and the second one presents a pivaloate at the 3-position hindering the β-face. Moreover, we also tested exoglycals 14 and 15 (Figure 1) whose synthesis had been previously described.1,4

![Figure 1](image)

**Figure 1**

**Hydrogenations of the exoglycals**

The results of the hydrogenation experiments from exoglycals 7 to 15 are summarized in Table 1. The structures of the major products and some side-products are represented in Figure 2.

![Figure 2](image)

**Figure 2**

We first had to find the most efficient catalyst for this reaction (Table 1, entries 1 to 4). Exoglycal 13, presenting a totally hindered α face and no bulky group on the β face was selected for this series. Interestingly, under high hydrogen pressure (100 bars) and vigorous stirring, the saturation of the enol ether was only observed with Pearlman's catalyst (entry 4), yielding ether 13a in 89% yield. A single diastereomer was observed by $^1$H and $^{31}$P-NMR of the crude final reaction mixture. The expected α configuration was unambiguously determined by the H1-H2 coupling constant ($J_{1-2} = 4.8$ Hz), indicating a cis relationship between these two protons. For β-configured galactofuranosides, the $J_{1-2}$ value would have been lower than 1.0 Hz.13,14 Moreover,
a NOESY experiment clearly showed a correlation between protons H-1 and H-4 of 13a, thus confirming the \( \alpha \)-configuration. Other standard homogeneous or heterogeneous catalysts (entries 1-3) either did not produce any product or yielded 10% of unidentified side-products. We then systematically performed this reaction with Pd(OH)\(_2\) (0.4 equivalent/w) in AcOEt at room temperature under H\(_2\) atmosphere (1.5 bar). Good to excellent yields (72 to 95%) have been obtained for the 9 starting exoglycals (entries 5 to 13). It should be noted that some side-products could be formed (Table 1, entries 5, 7, 8 and 11). We could isolate and characterize some of them (structures depicted in Figure 2). Interestingly, these molecules resulted from a migration of the double bond to give 2-alkoxy-endo-glycals. In one case, we could even isolate a furan 7c, likely resulting from an elimination of dihydrofuran 7b. These side-reactions are quite unusual and consequently the yields were not quantitative. Nevertheless, replacing AcOEt by MeOH as the solvent improved the yield and decreased the amount of side-products (entry 6).

(a) isolated yield. (b) determined by \(^1\)H- and \(^{31}\)P-NMR. (c) coupling constant of the \( \alpha \) isomer. (d) no reaction. (e) 10% conversion of the starting exo-glycal into two unidentified side-products. (f) unidentified side-products.

**Diastereoselectivity of the hydrogenations**

The exoglycals bearing a bulky protective group at the 2-position (Piv or TBDMS, molecules 7, 8, 13, 14 and 15) gave exclusively the " \( \alpha \) " C-galactosides. For each final ether, we performed NOESY experiments to confirm the "anomeric" configuration. In each case, a NOE effect
between protons H-1 and H-4 was observed which corroborated with the configuration assigned from $J_{1,2}$ coupling constants. Whatever the steric hindrance of the group at the 3-position (H, Piv or TBDMS), the addition occurred always from the $\beta$ face specifically. For all these molecules, the "$\beta$"-ether has never been observed. From this set of data, the steric hindrance at position 2 seems to be the only parameter governing the $\alpha$-specificity.

Then, we performed hydrogenations with a bulky pivaloate group at the 3-position and a less hindering functionality at the 2-position (OH, OCHO, OAc, entries 11, 12 and 13). Surprisingly, $\alpha$-diastereoselectivities were observed in the three cases, the $\beta$-phosphonate being formed, at best, in 20% yield. Exoglycal 10 gave a greater amount of side-products thus resulting in a poorer yield (entry 11). A better $\beta$-selectivity was expected with substrate 10 for two reasons: i) the steric hindrance of the OH group is rather small ii) OH groups have been shown to direct hydrogenations such a way that the H$_2$ addition occurs from the same face of a cyclic system. Clearly, this directing effect does not apply with Pearlman catalyst. The directing effect of hydroxyl groups for the hydrogenation reaction has been often observed with rhodium and iridium catalysts. We thus used Crabtree's and Wilkinson's catalysts, under basic or non-basic conditions, using alcohols 10, 13 and 14 as substrates. Unfortunately, the expected phosphonates were never formed under these conditions (data not shown).

In conclusion, this study showed that the hydrogenation of exoglycals in the galactofuranose series, even unprotected at the 2-position, give a good to excellent $\alpha$-selectivity. Other parameters than the relative steric hindrance of the two faces of the glycal may be invoked to explain this result: owing to the abundant literature related to the stereoselectivity of reactions taking place at the anomeric center, it is quite reasonable to suggest that stereoelectronic or conformational effects may strongly contribute to the systematic $\alpha$-selectivity we observed. Conformationally, furanoses are usually less restricted than pyranoses. However, the presence of a trigonal sp$^2$ hybridized anomeric carbon atom may favour a conformation placing the functional group in a position preventing the H$_2$ addition from the $\alpha$-face. Moreover, the mechanism of the hydrogenation under heterogeneous catalysis being still poorly understood, we cannot rule out a directing effect of the two free doublets of the endocyclic oxygen, in other words, a stereoelectronic effect favoring the addition from the $\beta$-face of these exoglycals.

**Experimental Section**

**General Procedures.** All chemicals were purchased from Sigma, Aldrich or Fluka and were used without further purification. Tetrahydrofuran and toluene were freshly distilled over sodium benzophenone, dichloromethane over P$_2$O$_5$ and nitromethane over CaH$_2$. $^1$H-, $^{13}$C- and $^{31}$P-NMR spectra were recorded with Bruker AC-250 and AMX-400 spectrometers. All new compounds were characterized by $^1$H, $^{13}$C, $^{31}$P-NMR as well as by $^1$H-$^1$H and $^1$H-$^{13}$C correlation experiments. Specific optical rotations were measured on a Perkin Elmer 241 Polarimeter in a 1 dm cell. Melting points were determined with a Büchi 535 apparatus. Purification by chromatography
was performed on silica gel Kieselgel Si 60 (40-63 µm) using cyclohexane (Cy) and AcOEt as eluent. Molecule 1 was prepared following literature data.\textsuperscript{10} Compounds 14, 15 and 15a were previously described.\textsuperscript{1,4}

Atom and position numberings. We systematically numbered the phosphonate methylene group 1’ and adopted the usual numbering for carbohydrates from 1 to 6 with 1 for the anomeric position.

General procedure for exoglycal formation from lactones

To a cooled (-70°C) solution of dimethyl methylphosphonate (1 eq.) in anhydrous THF (18 mL) under Ar was added first butyl lithium (1 eq., 2.5 M solution in hexane) and after 20 min, a solution of lactone (0.4 eq.) in anhydrous THF. The temperature was maintained at –70°C during 10 min, the reaction mixture was then allowed to reach –40°C over a 1 h period. The solution was then diluted with phosphate buffer (1 M, pH = 7) and extracted with CH\textsubscript{2}Cl\textsubscript{2}. The combined organic phases were dried over MgSO\textsubscript{4}, filtered and concentrated. The residue was dissolved in anhydrous CH\textsubscript{2}Cl\textsubscript{2}. At 0°C were added pyridine (10 eq.) and trifluoroacetic anhydride (5 eq.). After 3 h at 0°C, the reaction was stopped by addition of saturated aqueous NaHCO\textsubscript{3} followed by extraction with AcOEt. The organic phase was dried over MgSO\textsubscript{4}, filtered and concentrated at reduced pressure. The exoglycal was purified by chromatography on silica gel with cyclohexane/AcOEt (2:1).\textsuperscript{1,4}

General procedure for exoglycals hydrogenation

To a solution of exoglycal in AcOEt (final concentration 0.15 M), was added wet Pd(OH)\textsubscript{2} (0.4 equiv./w) and the resulting suspension was degassed three times (the solution was left a few seconds under vacuum then under H\textsubscript{2} atmosphere). The suspension was vigorously stirred under H\textsubscript{2} (1.5 bar) for 24 hours, filtrated over celite and concentrated under vacuum.

2-\textit{O-tert-Butyldimethylsilyl}-5,6-\textit{O-(dimethyl-methylidene)-D-galactono-1,4-lactone} (2). A suspension of lactone 1\textsuperscript{10} (890 mg, 4.08 mmol), TBDMSI (1.65 g, 4.28 mmol, 1.05 eq.) and imidazole (415 mg, 6.11 mmol, 1.5 eq.) in anhydrous DMF (12 mL) was stirred, under argon, one hour at 0°C, then overnight at room temperature. The solvent was removed and the resulting mixture was suspended in ether (15 mL) and washed twice with water (10 mL). The organic layer was dried over MgSO\textsubscript{4}, filtered and concentrated. The resulting crude reaction mixture was submitted to purification by chromatography on silica gel (Cy/AcOEt : 3/1) to give 2 (880 mg, 85 %) as a white solid. [\(\alpha\)\textsubscript{D}\textsuperscript{23}] = -7.1 (c 1.0, CHCl\textsubscript{3}); m.p. 118°C; \textsuperscript{1}H-NMR (400 MHz, CDCl\textsubscript{3}) \delta 4.42 (d, \textit{J}\textsubscript{2-3} = 8.5 Hz, 1H, H-2), 4.39 (td, \textit{J}\textsubscript{4-5} = 3.9 Hz, \textit{J}\textsubscript{5-6ab} = 6.8 Hz, 1H, H-5), 4.32 (dd, \textit{J}\textsubscript{2-3} = 8.5 Hz, \textit{J}\textsubscript{3-4} = 8.1 Hz, 1H, H-3), 4.13 (ABX, \textit{J}\textsubscript{5-6a} = 6.8 Hz, \textit{J}\textsubscript{6a-6b} = 8.7 Hz, 1H, H-6a), 4.10 (dd, \textit{J}\textsubscript{3-4} = 8.1 Hz, \textit{J}\textsubscript{4-5} = 3.9 Hz, 1H, H-4), 4.00 (ABX, \textit{J}\textsubscript{5-6b} = 6.8 Hz, \textit{J}\textsubscript{6a-6b} = 8.7 Hz, 1H, H-6b), 1.44, 1.40 (2s, 6H, C(CH\textsubscript{3})\textsubscript{2}, acetonide), 0.96 (s, 9H, Si-\textit{t}Bu), 0.16 (s, 3H, Si-Me), 0.13 (s, 3H, Si-Me); \textsuperscript{13}C-NMR (100 MHz, CDCl\textsubscript{3}) \delta 172.57 (C-1), 110.16 (C(CH\textsubscript{3})\textsubscript{2}, acetonide), 78.35 (C-4), 75.56.

Acknowledgements

We warmly thank Professor Krief and his team for sharing their facilities and for their stimulating scientific discussions. This work was supported by the Centre National de la Recherche Scientifique (CNRS, France), by the Ministere Delegue à la Recherche et aux Nouvelles Technologies (PhD grant to A.C.) as well as the University of Namur (post-doctoral grants to W.P.).
