Abstract

Strategically substituted indene derivatives are useful building blocks for high efficiency olefin polymerization metallocene catalysts. In this paper, various 4-aryl-substituted 2-methyl-1*H*-indanones were prepared efficiently using a ligand-free palladium-catalysed Suzuki coupling procedure. Quantitative yields of indanone intermediates were achieved for most of the non-coordinative substrates with a loading of 0.005 mol% of palladium catalyst. The corresponding indene derivatives were obtained in high purity and multi-gram scale in excellent yields, following a simple sequential reduction and dehydration procedure.

Keywords: Suzuki coupling, ligand-free palladium catalysis, metallocenes, polymerization

Introduction

Among numerous highly active homogeneous olefin polymerization catalysts, racemic dimethyl-silyl-bridged bis-2-methyl-4-phenylindenyl ZrCl₂, (Figure1) reported by the Hoechst team in the early 1990s, acts as a cornerstone in isospecific propylene polymerization catalysis, producing isotactic polypropylene (iPP) with significantly high catalytic activity, high molecular mass, high iso-specificity, and high melting point for industrial applications. Known results have shown that methyl and phenyl substitutions are responsible for superior performance of the catalysts in respect of high molecular weight, isotacticity and activity.¹⁻³ Subsequent research found that the pre-catalyst **1** is also a versatile catalyst for the preparation of olefin copolymers⁴⁻⁸ or heteroatom containing functionalized copolymers,⁹⁻¹⁴ which could potentially be used for the substitution of

PS, PVC, polydiene and related copolymers or as specialty materials (for example coatings, blends, composites, or ion exchange membranes, etc.). Other metallocenes based on **1** have appeared since 1990, and intensive studies of substitution effects for all possible positions of the indene framework were carried out. Much better catalytic performances were achieved and the polymers or co-polymer materials so generated exhibit pronounced improvements of PP properties (melting temperature, molecular mass, uniform monomer distribution, comonomer incorporation, *et al.*).^{2,3,15-18}

Figure 1. The Hoechst catalyst.

The critical dependence of the activity and selectivity of a metallocene on its ligand structure, especially the fact that some of the C_1 symmetric analogues exhibit boosted catalytic performances compared with their C_2 symmetric counterparts, have stimulated continuing efforts to develop fast and reliable ligand synthetic processes. Many research groups have developed diverse coupling procedures for the synthesis of substituted indenenes, based on abundant starting materials and highly efficient organic transformations. There are several strategies applied according to different coupling precursors:

A) From the coupling of 2-functionalized toluenes with desired aryl partners, a reliable sequential procedure was established and a number of indene ligands were prepared. However, many repeated operations are needed to evaluate catalysts with various aryl substitutions. In addition, undesired side reactions may occur for some sensitive substrates during the tedious process. For example, an extremely low yield was observed during the preparation of 2-methyl-4-(1-naphthyl)indanone using the above mentioned procedure;^{1,19}

B) As an important improvement, phosphine- or nitrogen-containing palladium complexes catalyzed Suzuki–Miyaura coupling of 4/7-halo indanones was widely applied in 4/7-aryl indene syntheses. Nevertheless, extra ligands used in these reactions caused additional limits such as inert atmosphere protection, more complex purification procedures or higher catalyst loadings.^{7,18,20,21}

C) Alexander *et al.* reported an impressive procedure of catalyzed coupling of 4/7 functionalized indenenes or indanes with arylboron, halogen, zinc, or magnesium reagents, using metal complexes, as the key step, affording 4-/7-aryl-substituted indenenes in excellent yields. This method has been

widely used in novel indene ligand synthesis. However, besides the above-mentioned limits with method **B**, the use of organometallic reagents greatly narrows the substrate scope.²²⁻²⁴

D) As the most straightforward strategy, bromo-substituted Group 4 metallocenes can be efficiently coupled with organo-zinc reagents following a Negishi coupling procedure. However, strikingly lower isolated yields were obtained for some of the substrates because of their sensitivity or isolation problems (Scheme 1).²⁵⁻²⁷ Most of these methods need extra ligands to stabilize the palladium catalysts, relatively high noble metal catalyst loading (2-6 mol%) and some of the organometallic reagents utilized severely limit the reaction conditions and the substrate scope.

Scheme 1. General methods for Ar-Ar bond formation in metallocene synthesis.

In recent years, many computational studies have been reported aimed at understanding olefin polymerization mechanisms, which have stimulated the development of novel metallocenes useful for new plastic material production.²⁸⁻³¹ In our continuing efforts to develop highly efficient metallocene catalysts based on theoretical computation and high-throughput methods for specialty polyolefins, a simple and efficient synthesis of high purity 4/7-arylindene derivatives is, undoubtedly, of great importance. In this respect, special attention has been paid to 4-arylindanones **4**, which can easily be converted into substituted 7-arylindenes **5** and thence into electron-rich ligands **6** following known procedures (Scheme 2). Moreover, the brominated indanones **2** could easily be prepared from abundant commercially available materials. Also, the electron-withdrawing property of the ketone group facilitates the oxidative addition of aryl bromide to the palladium center, which in most cases is known as the rate determining step in the catalytic cycle (Scheme 3).³²⁻³⁵ PEG-mediated ligand-free Suzuki coupling reactions are attractive because they avoid the use of a complex ligand, thus reducing the residue of harmful and costly noble metals in the final product and simplifying work-up procedures.³⁶⁻³⁹

We report here a highly efficient ligand-free catalytic system for the Suzuki coupling of 4-bromo-2-methyl-1*H*-indanone with aryl/heteroaryl boronic acids in a tetrabutylammonium bromide (TBAB)/Pd(OAc)₂/PEG400 system. Most of the reactions were complete in one hour at 110 °C without inert gas protection. Following a prototype reduction and dehydration procedure, the final 7-aryl-2-methyl-1*H*-indene products could be prepared in excellent yields. Multi-gram

scale reactions of 4-bromo-2-methyl-1*H*-indanone with 3,5-bis(trifluoromethyl)phenylboronic acid as the substrate proceeded smoothly, and the substituted indene was prepared in very high total yield for three steps without fractional distillation or column chromatography.

Results and Discussion

The Suzuki coupling of 4-bromo-2-methylindan-1-one with phenylboronic acid (**8a₀**) in a PEG400/ $\text{Pd}(\text{OAc})_2$ /TBAB system was chosen as the model reaction and various parameters were evaluated (Equation 1). The reaction yield improved from 17% to 98% in one hour at elevated temperatures (from 80 °C to 110 °C). *In situ* generated nano palladium particles, whose surface properties are unambiguously affected by reaction temperature, have been proved to be active catalysts (Table 1 entries 1, 2).³⁴ Of those tested, potassium carbonate was the base of choice, providing the highest product yields (Table 1, entries 2-5), while potassium hydroxide was a poor base for the coupling (Table 1, entry 3). Sodium carbonate and potassium phosphate also gave good yields (Table 1, entries 4, 5). In addition, the effect of TBAB on the reaction was examined under otherwise identical conditions; reactions without TBAB or decreasing its loading to 10

mol% furnished the coupled product in lower yields. Reported results showed that TBAB played a dual role for the reaction, as phase transfer catalyst and also as a nano-palladium stabilizer (Table 1, entries 6, 7). Surprisingly, on reducing the loading of the noble metal catalyst precursor Pd(OAc)₂ from 0.1 mol% to 0.01 mol%, or even to as low as 0.005 mol%, identical catalytic productivities were achieved under otherwise identical reaction conditions. Further decreasing the catalyst loading to 0.001 mol% resulted in a lowered yield of coupling product (53% in three hours). To the best of our knowledge, this is one of the most efficient methods for this kind of indanone synthesis to date (Table 1, entries 8, 9, 10). As a comparison, the same coupling was performed under the commonly used oxygen-free coupling conditions with 0.1 mol% of Pd(PPh₃)₄ as the catalyst, and 90% of coupling yield was obtained in five hours (Table 1, entry 11).

To our satisfaction, all the coupling reactions proceeded smoothly with substituted phenylboronic acids containing either electron-withdrawing or -donating groups (CN, CF₃, *t*-Bu, OMe, *et al.*) with 0.005 mol% of catalyst loading in 84-97% isolated yields (Table 2, entries 1-18). For 2-Cl, 3-Cl or 3-NO₂ phenylboronic acid, slightly elevated Pd(OAc)₂ loading (0.01 mol%) is necessary for satisfactory coupling yields (80-90%, Table 2, entries 19-21). Generally, the *ortho* substituted phenylboronic acids produced a somewhat inferior result to their *meta* and *para* substituted congeners, thus the reaction of 2-trifluoromethylphenylboronic acid needed as high as 5 mol% of catalyst loading to deliver sufficient catalytic productivity (79% yield). We ascribed this to the stereo-hindrance effect of the substrates (Table 2 Entries 1,3,9,19,22). 2-Naphthaleneboronic acid and heteroaryl boronic acids proved to be good candidates for the current coupling with 1-5 mol% of catalyst precursor (Table 2, entries 23 - 28). The furan ring had much less effect on the reactivity than did N-containing heterocycles; thus with 0.01 mol% of catalyst loading, the reaction was complete within 30 minutes to give the desired product in 90% isolated yield (Table 2, entry 29).

7-Aryl-2-methyl-1*H*-indenenes were prepared following a reduction/dehydration procedure (Equation 3) and the results are listed in Table 3.

Most of the reactions proceeded smoothly and produced the desired indene products in excellent yields. It should be noted that higher concentrations in the dehydration step may promote undesirable side reactions, especially for some electron-rich substrates.

Considering the solubility differences of PEG400, Pd(OAc)₂, TBAB, arylboronic acids, substituted indanones and related indenenes, developing a fast and highly efficient 7-aryl-2-alkyl-1*H*-indene synthetic procedure with simple purification operations is highly desirable. To this end, 3,5-bis(trifluoromethyl)phenylboronic acid was chosen as the model substrate for a multi-gram scale (4.5 g, 20 mmol) synthesis following the current procedure. According to previous results, the couplings were fast, clean and previously observed side reactions, such as debromination and/or de-boronation were, to our surprise, not observed; thus the aryl boronic acid was used in slight excess (1.05 eq.). As expected, the reaction proceeded smoothly at higher concentration and was accomplished with only 0.005 mol% of catalyst loading. After normal extraction and evaporation, complete removal of residual PEG400, Pd(OAc)₂, TBAB and aryl boronic acid was achieved by washing with cold methanol. After the reduction and dehydration protocol, the crude product was washed again with methanol to give 86% of pure indene derivative **10a₁₅** as a white crystalline material (Scheme 4).

Conclusions

A ligand-free Suzuki coupling system consisting of PEG-400/Pd(OAc)₂/TBAB/K₂CO₃ in optimized ratio was employed for the Suzuki-Miyaura coupling reaction of 4-bromo-2,3-dihydro-2-methyl-1*H*-inden-1-one (**7**) with aryl and/or heteroarylboronic acids. Most of the substituted phenylboronic acids reacted smoothly with 0.005 mol% of catalyst loading, and all the reactions were accomplished within a period of 0.5–3 hours in excellent yields (82–98%). Some of the heteroarylboronic acids also reacted in good to excellent yield (59–90%) with controlled low catalyst loading (0.01–5 mol%). The intermediate indanones could be easily transformed into their indene derivatives in high purity and high productivity. Multi-gram scale reaction of **8a₁₅** was conducted following our typical Suzuki-Miyaura coupling, reducing and dehydrating procedures without fractional distillation or column chromatographic purification. Pure substituted indene **10a₁₅** was obtained in high yield. Coupling of more complex substituted indanones with

arylboronic acids following the current procedure is in progress and the catalytic properties of newly prepared novel C1 and C2 symmetric metallocenes are under evaluation.

Experimental Section

General. Melting points were measured on a Novel X-5 melting point instrument. All ^1H NMR (400 MHz) and ^{13}C NMR (100 Hz) spectra were measured in CDCl_3 and recorded on Bruker Avance II 400 (^1H NMR) spectrometer with chemical shifts reported as ppm (with TMS as an internal standard). Purification of the reaction products was carried out by flash chromatography (FC) on silica gel (200-300 mesh). HRMS were conducted on GCT mass spectrometer (EI). All reactions were carried out in air and using distilled solvents, without any precautions to exclude moisture unless otherwise noted. Commercial grade reagents and solvents were used without further purification; otherwise, where necessary, they were purified as recommended.

Typical procedure for 7-aryl-2-methyl-1H-indene synthesis

To a solution of 2,3-dihydro-2-methyl-4-phenyl-1H-inden-1-one **9a₀** (222.3 mg, 1.0 mmol) in 15 mL of THF/MeOH (2:1), was added 114 mg (3.0 mmol, 3.0 eq.) of NaBH_4 in portions at 0 °C. The reaction mixture was warmed slowly to rt and stirred till completion (TLC). The solvent was evaporated and 10 mL of water was added. The mixture was extracted with EtOAc (10 mL X 2). The combined organic extracts were dried and evaporated. The residue was taken up in 50 mL of toluene and mixed with 100 mg of TsOH monohydrate. The formed mixture was refluxed with Dean-Stark head for 2 h. 30 mL of ethyl acetate was added and the resulting solution was washed with Na_2CO_3 (10%). The organic layer was separated and the aqueous layer was extracted with EtOAc (30 mL X 2). The combined organic extracts were dried and then filtered through a short pad of silica gel. The solvent was evaporated to give pure 2-methyl-7-phenyl-1H-indene **10a₀**. yield: 73 %, 151 mg, colorless oil. ^1H NMR (CDCl_3 , 400 MHz) δ_{H} : 7.53 (2H, d, $^3J_{\text{HH}}$ 7.1 Hz, ArH), 7.44 (2H, t, $^3J_{\text{HH}}$ 7.5 Hz, ArH), 7.35 (H, t, $^3J_{\text{HH}}$ 7.4 Hz, ArH), 7.30 (H, d, $^3J_{\text{HH}}$ 7.4 Hz, ArH), 7.25 (H, d, $^3J_{\text{HH}}$ 5.8 Hz, ArH), 7.13 (1 H, t, $^3J_{\text{HH}}$ 7.5 Hz, ArH), 6.54 (1H, s, ArCH), 3.38 (2H, s, ArCH_2), 2.14 (3H, s, CCH_3).

Multi-gram scale synthesis of 10a₁₅ without fraction distillation or column chromatography

Into a 100 mL round-bottom flask, was filled with a mixture of 4-bromo-2-methyl 1-indanone **7** (4.50 g, 20 mmol), 3,5-ditrifluoromethyl phenylboronic acid **8a₁₅** (5.40 g, 21 mmol, 1.05 eq.), Pd(OAc)₂ (0.225 mg, 1.0 μmol , 0.005 mol%), TBAB (7.16 g, 20 mmol, 1.0 eq.), K₂CO₃ (5.53g, 40 mmol, 2.0 eq.) and PEG400 50 g. The mixture was stirred at 110 °C till completion (TLC). 50 mL of water was added and the contents were extracted with EtOAc (100 mL X 3). The organic phase was washed with brine (100 mL X 2), dried over Na₂SO₄ and concentrated to dryness. 20 mL of methanol was added and the suspension was stirred overnight. After filtration, the white solid was dissolved in 300 mL of THF/MeOH (2:1) and 1.14 g (30 mmol, 1.5 eq.) of NaBH₄ was added in portions at 0 °C. The reaction was stirred at rt till completion (TLC). After evaporation, the residue was partitioned between EtOAc and H₂O (200 mL, 1:1). The aqueous phase was extracted with EtOAc (100 mL $\times$ 2). The combined organic extracts were dried and evaporated to dryness. The crude product was taken up in 350 mL of toluene and mixed with 200 mg of TsOH monohydrate. The formed mixture was refluxed with Dean-Stark head for 5 h. Toluene was removed under reduce pressure and the residue was re-dissolved in EtOAc/MeOH (200 mL, 1:1). The aqueous phase was extracted with EtOAc (100 mL $\times$ 2). The combined organic extracts were washed subsequently with saturated NaHCO₃ (100 mL $\times$ 2), brine (100 mL $\times$ 2) and dried over Na₂SO₄. After evaporation, the residue was suspended in methanol (15 mL) and stirred overnight. The slurry was filtered to yield 2-methyl-7-(3,5-bistrifluoromethylphenyl)indene **10a₁₅** 5.9 g (17.2 mmol) in 85.8% yield.
