Abstract

N-Substituted 2-exo-hydroxybornyl-10-sulfonamides, prepared as potential chiral auxiliaries for use in asymmetric Morita-Baylis-Hillman (MBH) reactions, have been treated with acryloyl chloride to afford the corresponding 2-exo-acrylate esters as MBH substrates. Reaction of selected 2-exo-acrylate ester substrates with pyridine-4-carbaldehyde and 6-methylpyridine-2-carbaldehyde in the presence of DABCO gave the expected MBH adducts in > 91% yield and with diastereoselectivities of 7-33% d.e.

Introduction

The conformational rigidity and steric demands of the bicyclic camphor system account for its use in the construction of a wide range of chiral auxiliaries. These include Oppolzer’s classic camphorsultams and the sterically hindered systems developed by Helmchen. In earlier studies, we have explored the application of camphor-derived chiral auxiliaries in the asymmetric α-benzylation of carboxylic esters prepared using the borneol derivative, Simmons-Smith asymmetric cyclopropanation of α,β-unsaturated acetics prepared using the chiral diol, and preliminary asymmetric Morita-Baylis-Hillman (MBH) reactions involving chiral acrylate esters. The chiral auxiliary used in these preliminary MBH reactions was the N-adamantyl-2-exo-hydroxybornyl-10-sulfonamide, and the promising level of diastereoselectivity observed in one of these reactions prompted us to investigate the preparation of a series of N-substituted analogues as potential chiral auxiliaries for asymmetric MBH reactions.
Results and Discussion

Synthetic access to the series of chiral auxiliaries 7 and 8 and the corresponding acrylate ester derivatives 9 and 10 is outlined in Scheme 1. Thus, each of primary or secondary amines 5a-j was treated with (1S)-(−)-camphor-10-sulfonyl chloride (4) in the presence of a catalytic quantity of 4-(dimethylamino)pyridine (DMAP) in acetonitrile. Work-up and purification furnished the corresponding N-substituted camphor-10-sulfonamides 6a-j in good to excellent yields (83-100%; Table 1). Reduction of the carbonyl group in each of the N-substituted camphor-10-sulfonamides 6a-j was effected using NaBH₄ to afford the epimeric 2-hydroxybornyl-10-sulfonamides 7a-j and 8a-h,j in moderate to excellent yields (53-100%) and, generally, with high diastereoselectivity (100% in the case of the 2-imidazolyl derivative 7i), as shown in Table 1. The dicyclohexyl derivative 7j has been used previously as a chiral auxiliary by Oppolzer et al. in asymmetric Diels-Alder reactions⁷ and in the asymmetric synthesis of aldols,⁸ halohydrins and epoxides,⁹ and α-amino acids.¹⁰ Semi-preparative HPLC permitted isolation of analytical samples of the 2-exo- and 2-endo-hydroxy epimers, eight of which are new compounds. The C-2 configurations assigned to these epimeric products are supported by their ¹H NMR chemical shift and coupling constant data. Dominance of the 2-exo-hydroxy epimers 7 may be attributed to preferential hydride delivery to the less hindered endo face of the carbonyl group in the ketone precursors 6.

Scheme 1. Reagents and conditions: i) DMAP, CH₃CN, 0 °C; ii) NaBH₄, EtOH-H₂O, 0 °C; iii) Al₂O₃, CH₂=CHCOCI; and iv) in situ HCl.
Formation of the acrylate esters 9 and 10 was achieved as reported previously. The alcohols 7 and 8 were added, generally as epimeric mixtures, to neutral Al₂O₃ (1.5 eq.), followed by acryloyl chloride (2 eq.). The resulting dispersions were allowed to stand at r.t. for 72 h without stirring. Flash chromatographic separation of the products, following work-up, proved impossible, necessitating the use of semi-preparative HPLC to obtain analytical samples; even then, the products, in some cases, remained slightly contaminated. The major products were, typically, the 2-exo-acryloyloxybornane-10-sulfonamides 9 and their 2-exo-[(3-chloropropanoyl)oxy]bornane-10-sulfonamide derivatives 11, the latter arising from conjugate addition to the former by the HCl released as a by-product. [We have shown previously that dehydrochlorination (11 → 9) can be readily achieved using triethylamine.] Minor products, isolated in some cases, included the 2-endo-[(3-chloropropanoyl)oxy]bornane-10-sulfonamide derivatives due to the presence of low concentrations of the 2-endo alcohols in the substrate mixtures.

In the present study, attention was focused on using the 2-exo-acryloyloxybornane-10-sulfonamides 9a,b,f as chiral MBH substrates. Pyridinecarbaldehydes tend to react rapidly under MBH conditions, and pyridine-4-carbaldehyde and 6-methylpyridine-2-carbaldehyde were selected as the electrophiles and the tertiary amine, DABCO, as the nucleophilic catalyst for these reactions (Scheme 2). The reactions were allowed to run for 90 h and the desired series of MBH adducts 12 and 13 were obtained with excellent conversion levels (91-100%) as determined by 1H NMR analysis after preliminary flash chromatography of the reaction mixtures. The diastereoselectivities were determined by comparing the relative integrals of the signals.
corresponding to the vinylic methylene and hydroxymethine protons (between 5 and 6 ppm) in the 1H NMR spectra of the mixtures of the major and minor MBH products. The results, summarised in Scheme 2, reveal that while a measure of diastereoselectivity (7-33% d.e.) was observed in all cases, there is considerable room for improvement, and careful optimisation of the methodology is required to establish reproducibility of our encouraging, preliminary results (up to 95% d.e.) obtained earlier. As observed previously, reactions with the more sterically hindered aldehyde, 6-methylpyridine-2-carbaldehyde exhibit significantly higher diastereo-selectivities than reactions with pyridine-4-carbaldehyde, confirming the expectation that steric effects play a major role in diastereococontrol. It is expected that future efforts will focus on using inter- and/or intramolecular coordination effects to increase transition-state rigidity and thus enhance diastereoselectivity in such MBH reactions.

Conclusions

A number of borneol derivatives have been prepared with the potential to serve as chiral auxiliaries in various transformations, and the use of three of these compounds has been explored in asymmetric MBH reactions. Future challenges include the optimisation of reaction conditions and structural modifications to enhance diastereoselectivity.
Experimental Section

General. Reagents and solvents were used without further purification. ¹H and ¹³C NMR spectra were recorded on Bruker AMX400 or Avance II 600 MHz spectrometers, and were calibrated using solvent signals; coupling constants are given in Hertz (Hz). Melting points were determined using a hot-stage apparatus, and are uncorrected. IR spectra were recorded on a Perkin Elmer Spectrum 100 FT-IR spectrometer. High-resolution mass spectra were recorded at the University of Stellenbosch Mass Spectrometry Unit. Flash chromatography was carried out using Merck silica gel 60 [230-240 mesh (particle size 0.040-0.063 mm)] and preparative layer chromatography was conducted using silica gel 60 PF₂₅₄.

Compounds 6a,b,c,e,f,g,h,j, 7a,c,h,j, 8a,c, 12f and 13f are known.¹⁴-¹⁷ General procedures and analytical data for new compounds are as follows.

Formation of the camphor-10-sulfonamides 6a-j

General procedure, exemplified by the preparation of N-benzylcamphor-10-sulfonamide (6a). A solution of (+)-camphor-10-sulfonyl chloride (4) (10.0 g, 39.9 mmol) in acetonitrile (100 mL) was added dropwise under N₂ to a stirred solution of the benzylamine (5a) (8.67 mL, 79.5 mmol) and DMAP (1.28 g, 10.5 mmol) in acetonitrile (50 mL) at 0 °C. The solution was stirred for 1 h and water (50 mL) was then added, followed by 10% HCl (10 mL), and the resulting mixture was extracted with EtOAc (3 × 125 mL). The organic layers were combined, washed with 5% aqueous NaOH (25 mL) and dried over anhydrous MgSO₄. The solvent was removed in vacuo to afford the known N-benzylcamphor-10-sulfonamide (6a)¹⁴,¹⁵ as colourless crystals (12.8 g, 39.8 mmol, 99%).

General procedure, exemplified by the preparation of N-benzyl-2-exo-hydroxybornane-10-sulfonamide (7a) and N-benzyl-2-endo-hydroxybornane-10-sulfonamide (8a). A solution of N-benzylcamphor-10-sulfonamide (6a) (12.0 g, 37.3 mmol) in EtOH/H₂O (5:1) (104 mL) was added drop-wise to a
